Superimposing the three solutions (fig. 27) gives the boundary conditions- $\sigma_y = S(x) = S_0 + S_1 x + S_2 x^2$; $\sigma_{xy} = 0$, for $x = a$, $y = 0$. These driving-stress distributions for a single isolated crack result in a suitable range of cross-sectional forms and allow considerable insight into dike dilation and the subtle effects of stress gradients. The results, which we obtain as straightforward analytical expressions, make these simplifications attractive. Defining the dimensionless variables $X = x/a$ and $D(X) = 2u_0/a$, the important equations for our purposes are: $2D(X) = C_1(1-X^2)^{1/2} + C_2(i-x)h^2 + x^2n_x/i - a - x^2y^2$. The three terms on the right-hand side of equation 19/4 represent the contributions to the thickness of the crack from each of the three boundary conditions. The relative importance of these terms depends on the relative magnitudes of the three constants, C_1 , C_2 , C_3 , which may be either positive or negative but together must give a positive or zero thickness....

Reviews

This ebook will be worth acquiring. It is actually written in basic phrases instead of hard to understand. It is extremely difficult to leave it before concluding, once you begin to read the book.
