Springer. Paperback. Condition: New. 248 pages. Dimensions: 9.0in. x 6.0in. x 0.6in. Large Eddy Simulation is a relatively new and still evolving computational strategy for predicting turbulent flows. It is now widely used in research to elucidate fundamental interactions in physics of turbulence, to predict phenomena which are closely linked to the unsteady features of turbulence and to create data bases against which statistical closure models can be assessed. However, its applicability to complex industrial flows, to which statistical models are applied routinely, has not been established with any degree of confidence. There is, in particular, a question mark against the prospect of LES becoming an economically tenable alternative to Reynolds-averaged Navier-Stokes methods at practically high Reynolds numbers and in complex geometries. Aerospace flows pose particularly challenging problems to LES, because of the high Reynolds numbers involved, the need to resolve accurately small-scale features in the thin and often transitional boundary layers developing on aerodynamic surfaces. When the flow also contains a separated region - due to high incidence, say - the range and disparity of the influential scales to be resolved is enormous, and this substantially aggravates the problems of resolution and cost...
