Rarebooksclub.com, United States, 2012. Paperback. Book Condition: New. 246 x 189 mm. Language: English . Brand New Book ***** Print on Demand *****.This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1844 Excerpt: . be made in capacity the better; the limit of size being wholly dependent upon practical considerations of construction, and upon the power of rapid supply of steam to fill them. In the present case we have provided a capacity such that eleven trains may be passed before it becomes necessary to clear the condensor of air; it is therefore plain that if this operation were performed at every fifth train, the vessels might be of only one half the capacity here assigned. The generating power of the boilers being still the same, the rapidity of producing vacuum would be but little diminished. The question, however, of the most advantageous possible size of vessels under given conditions, is one requiring further investigation, based upon certain experiments which require to be made. We are now enabled to determine the amount of vacuum that we shall obtain in the six miles of 15-inch tube by the use of the apparatus. The capacity of the tube = 38872 cubic feet. $r = 38872$ cubic feet. $b = 19436$ cubic feet. $b = 95$ as before, we have for the first stroke $d = 0.687 \times 30 = 20.34$ inches of the rarefaction; Or assuming $r = 200$, and $b = 95$ as before, we have for the first stroke, $200 \div 95 + 200$ and hence the vacuum at the first stroke, $30 - 20.34 = 9.66$ inches of the vacuum-gauge. For the second stroke, $d = 0.458 \times 30 = \dots$
