They have been used with a varying degree of success to describe many types of phenomena encountered in applications. From the discussion in Chapter 1 it will be apparent that by using these schemes, it is possible to approximate a large and important class of stationary processes, viz. the so-called linear processes (see For this to be possible p must take large rather than small values and parameters involved in the scheme must be adjusted adequately. During the last ten years a good deal of work has been devoted to the construction of tests, estimates and confidence intervals appropriate for these schemes. We have described a few of the more important of these results in Chapter 3. In spite of the ingenuity and great theoretical interest of some of these methods, their practical applicability seems to be limited severely by the assumption that the process is a low (usually zero, first or second) order finite parameter scheme. After surveying a good deal of the applied literature devoted to statistical analysis of time series met with in practice, we have come to the following conclusion.
