Excerpt from Respiratory Care, Vol. 37: July, 1992 Volume-cycled Decelerating Flow: An Alternative Form of Mechanical Ventilation - SA Ravenscraft, WC Burke, JJ Marini. Chest 1992; The linearly decelerating flow wave form for volume-cycled mechanical ventilation is an option on many modern ventilators. We have developed mathematical models for two available forms of volume-cycled decelerating-flow ventilation (v cdf). These equations use clinician-chosen ventilator settings as inputs (frequency, tidal volume, peak inspiratory flow or inspiratory time fraction, and end-inspiratory pause), and patient-determined inputs that describe the patient's ventilatory impedance (inspiratory [ri] and expiratory [re] resistance and respiratory system compliance). The equations predict key outcome variables: mean airway pressure; and peak, mean, and end-expiratory alveolar pressures. The mathematical expressions were validated in a mechanical lung analog. Values observed in the test lung were compared to values predicted by the mathematical models for a wide range of ventilator settings and impedance combinations (ri and RE 5 to 40 cm H₂O s/l; C to L/cm H₃O). The correspondence between observed and predicted values was generally excellent across the broad range of inputs tested (r²0.98). Outcome variables were quite sensitive to clinician-chosen inputs over certain critical ranges. Carefully applied, vcdf offers several theoretic advantages for the clinical setting; however, appropriate caution must be exercised to avoid the application of tissue-injuring pressure.
