Rarebooksclub.com, United States, 2012. Paperback. Book Condition: New. 246 x 189 mm. Language: English . Brand New Book ***** Print on Demand *****.This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1905 Excerpt: $(1 + 0.005310 \sin^2 \theta)$ If then having observed g at any point of the earth's surface we can compute what the value would have been had the station of observation been at sea level, we can by comparing the value with g_0 ascertain whether the density of the underlying crust is in excess or defect of the average or normal surface density. If the station of observation were situated in a balloon floating over a level plain the only consideration to be taken Reduction to sea level. $g = g_0 - \frac{2\pi G \rho R^2}{3}$ into account would be the greater distance from the earth's centre. Now the attraction of a sphere of radius R on a point on its surface is $g_0 = \frac{GM}{R^2}$ where G is the attraction of unit mass. If the point is above the surface at a distance R by the height h the attraction becomes $g = \frac{GM}{(R+h)^2}$ Hence $g = g_0 \left(\frac{R}{R+h} \right)^2$ neglecting the term in h^2 . When, however, and this is the common case, the observations are made on terra firma we have to consider that between the surface of the sphere and the pendulum there is a quantity of matter which is exerting an attraction, and this must be allowed for before we can deduce from our observed g what the value of gravity at sea-level would be. If the station is on an extensive plain, or in country which does not...
